DVSA Vulnerability

Discovery & Remediation

ICS-344: Information Security | KFUPM | Term 252

Team Members: Lujain Aljehani • Meznah Alshubaian • Lamees Alharbi

DVSA URL: http://dvsa-website-577211135850-us-east-1.s3-website.us-east-1.amazonaws.com

Project Overview

What is DVSA?

OWASP Damn Vulnerable Serverless Application, a deliberately insecure app deployed on AWS for security training.

Our Goal

Identify, exploit, fix, and verify 10 official vulnerabilities in a real AWS serverless environment.

Architecture

S3 frontend → API Gateway → Lambda → DynamoDB. Vulnerabilities exist at every layer of this pipeline.

AWS Services Used:

- API Gateway
- Lambda
- DynamoDB
- S3
- Cognito
- IAM
- CloudWatch

10 Vulnerabilities

#01	Event Injection Lamees	FIXED	
#02	Broken Authentication Meznah	FIXED	
#03	Sensitive Data Exposure Lamees	FIXED	
#04	Insecure Cloud Config Meznah	FIXED	
#05	Broken Access Control Meznah	FIXED	
#06	Denial of Service Lujain	FIXED	
#07	Over-Privileged Functions Lujain	FIXED	
#08	Logic Vulnerabilities Lujain	FIXED	
#09	Vulnerable Dependencies Lamees	FIXED	
#10	Unhandled Exceptions Lujain	FIXED	

#01

Event Injection & Vulnerable Dependencies

Affected: DVSA-ORDER-MANAGER Lambda / node-serialize package

Exploit

Sent a malicious payload using the _$$ND_FUNC$$_ marker through the /order API. The node-serialize library evaluated and executed the injected JavaScript function during deserialization, before any application logic ran.

Result: CloudWatch logs confirmed LAMEES_LESSON_1_SUCCESS — proving arbitrary code executed on the Lambda backend.

Fix Applied

Replaced serialize.unserialize() with JSON.parse() in DVSA-ORDER-MANAGER/order-manager.js for both request body and headers. JSON.parse() only parses data and never evaluates functions, completely eliminating the injection vector.

Verified

After the fix, the same injection payload was sent again. CloudWatch logs showed only START, END, and REPORT entries with no LAMEES_LESSON_1_SUCCESS message. The injected function no longer executes.

#02 Broken Authentication

Affected: DVSA-ORDER-MANAGER Lambda / JWT handling

Exploit

Captured a valid JWT for User B. Decoded the payload, replaced username and sub fields with User C's identity, re-encoded it with the original signature (B).

Result: The backend accepted the forged token and returned User C's order details.

Fix Applied

Added JWT signature verification using trusted public keys. The backend now verifies the signature and validates issuer and expiry before trusting any claim.

Verified

The forged token now returns an error (invalid token). A legitimate token still works normally, but User B can no longer access User C's orders.

#03 Sensitive Information Disclosure

Affected: DVSA-ADMIN-GET-RECEIPT Lambda / S3 signed URLs

Exploit

As a regular non-admin user, called the get-receipt action on the /order API with a valid order ID, year, month, and day. The DVSA-ADMIN-GET-RECEIPT function was invoked with no authorization check.

Result: Received a pre-signed S3 URL and downloaded a zip file containing a real receipt — customer name (Lamees), address (123 Test St), item (Super Mario 2), total ($45).

Fix Applied

Added if (!isAdmin) authorization check in the get-receipt case of DVSA-ORDER-MANAGER/order-manager.js. If the user is not an admin, the function returns 403 Forbidden immediately without ever invoking DVSA-ADMIN-GET-RECEIPT.

Verified

Non-admin users can no longer generate receipt URLs for other users' orders. Unauthorized requests now return a 403 Forbidden response.

#04 Insecure Cloud Configuration

Affected: S3 bucket / Lambda function (DVSA-SEND-RECEIPT-EMAIL)

Exploit

Uploaded a malicious file directly to the DVSA S3 bucket due to weak bucket access policies. The file was processed by a Lambda function.

Result: Attacker ‘s file content was executed and processed by the backend Lambda.

Fix Applied

Enabled block public access in S3. Added filename validation (ends with .raw and contains _). Replaces unsafe execution with safe file handling.

Verified

Attempts to upload malicious files to the bucket are now denied. The Lambda function no longer processes unvalidated attacker-controlled files.

#05 Broken Access Control

Affected: DVSA-ADMIN-UPDATE-ORDERS Lambda function

Exploit

The DVSA-ADMIN-UPDATE-ORDERS function was accessed through a normal user request using the API. The order status was changed to “paid” without completing the payment process.

Result: Order appeared as paid without any actual payment.

Fix Applied

The DVSA-ADMIN-UPDATE-ORDERS function is now protected by role checks.
Order status updates are only allowed for authorized users.
Requests from public functions are blocked from performing admin operations.

Verified

Regular users can no longer call the admin update function. Attempting to change order status without payment now returns an error (unknown action).

#06 Denial of Service

Affected: DVSA-ORDER-BILLING Lambda / API Gateway

Exploit

Sent 50 concurrent billing requests simultaneously using curl with & operator. The billing Lambda was overwhelmed and crashed.

Result: Mass 500 Internal Server Errors. Legitimate users could not complete checkout.

Fix Applied

configured API Gateway dvsa stage throttling: Rate 5, Burst 10.

Verified

Running the same 50 concurrent requests now produces 429 Too Many Requests responses, confirming the rate limit is blocking excessive requests.

#07 Over-Privileged Functions

Affected: DVSA-SEND-RECEIPT-EMAIL Lambda / IAM Role

Exploit

Reviewed the role of DVSA-SEND-RECEIPT-EMAIL. Found policies that apply to all resources (using '*').

IAM Policy Simulator confirmed:
S3 GetObject/PutObject Allowed on ANY bucket.
DynamoDB Scan/Delete Allowed on ANY table.

Its beyond what a receipt email needs.

Fix Applied

Restricted SendReceiptFunctionRolePolicy1 to only dvsa-receipts bucket.

Restricted Policy2 to only GetItem on DVSA-ORDERS-DB table.

Replaced Policy3 with specific SES send permissions.

Removed AmazonSESFullAccess managed policy.

Verified

IAM Policy Simulator now shows Denied for S3 buckets and DynamoDB tables.

The function can only access the specific resources it needs.

#08 Logic Vulnerabilities (Race Condition)

Affected: DVSA-ORDER-UPDATE Lambda / DynamoDB

Exploit

Sent a billing request and an update request simultaneously.

Billing processed payment for 1 item while update changed quantity to 5.

DynamoDB confirmed: itemList = 5 items, totalAmount = $0.

Got 5 items while paying for 1.

Fix Applied

Fix in DVSA-ORDER-UPDATE:
1. Status check: rejects update if orderStatus != 100

2. DynamoDB conditional update by checking both status and absence of paymentTS.

Verified

The update request now returns 'Order cannot be modified (payment in progress)'.

DynamoDB conditional update blocks concurrent modifications at the database.

#09 Vulnerable Dependencies

Affected: DVSA-ORDER-MANAGER Lambda / node-serialize

Exploit

The node-serialize package in DVSA-ORDER-MANAGER was used to deserialize attacker-controlled input. Its $$ND_FUNC$$ marker causes it to evaluate JavaScript functions during deserialization — a dangerous capability never intended for untrusted input.

Result: A single crafted JSON request caused remote code execution entirely because of an unsafe third-party library.

Fix Applied

Replaced serialize.unserialize() with JSON.parse() in order-manager.js. JSON.parse() is a built-in safe alternative that never evaluates functions. The node-serialize library is no longer in the request path.

Verified

After the fix, the same injection payload was sent. CloudWatch logs showed only START, END, and REPORT entries — no LAMEES_LESSON_1_SUCCESS message. The vulnerable dependency no longer poses a risk.

#10 Unhandled Exceptions

Affected: DVSA-ORDER-BILLING and DVSA-ORDER-GET Lambda

Exploit

Sent malformed requests to two endpoints:

- Billing with no real cart total: KeyError: 'total' leaked from order_billing.py line 64
- Get order with wrong type: AttributeError leaked from get_order.py line 32

Internal file names, line numbers, and source code exposed to anyone.

Fix Applied

Added try/except in order_billing.py around cart total calculation returning only a generic error message.

Fixed get_order.py with isAdmin handling.

All internal errors now logged to CloudWatch only.

Verified

Both endpoints now return generic messages with no internal details.

Before: full stack trace with file paths and code.

After: {status: err, msg: could not process order}.

Key Takeaways

Verify, Don't Trust

Never trust JWT claims without verifying the signature. Unverified tokens are the same as no authentication.

Least Privilege

Every Lambda function should only have permissions for exactly what it needs.

Lock Critical Operations

Use conditional updates and locking to prevent race conditions in workflows with multiple steps.

Rate Limiting is Essential

Serverless functions have no DoS by default. Always add throttling at the API Gateway and Lambda level.

Never Expose Internals

Catch all exceptions and return only generic messages to users and log full details to CloudWatch.

Audit Dependencies

Third-party packages can introduce critical vulnerabilities. Regularly scan and replace unsafe libraries.
